"Mathematically, Metcalfe's Law shows that the number of unique possible connections in an n -node connection can be expressed as the triangular number $\frac{n(n-1)}{2}$, which is asymptotically proportional to n^2 . The law has often been illustrated using the example of fax machines: a single fax machine on its own is useless, but the value of every fax machine increases with the total number of fax machines in the network, because the total number of people with whom each user may send and receive documents

increases. This is common illustration to explain network effect. Thus, in any social network, the greater the number of users with the service, the more valuable the service becomes to the community. History and derivation Metcalfe's law was conceived in 1983 in a presentation to the 3Com sales force. It stated V would be proportional to the total number of possible connections, or approximately n -squared."
