"A given cryptocurrency's susceptibility to attack depends on the existing hashing power of the network since the attacker needs to overcome it. For the attack to be economically viable, the market cap of the currency must be sufficiently large to justify the cost to rent hashing power. In 2014, mining pool GHash.io obtained 51% hashing power in Bitcoin which raised significant controversies about the safety of the network. The pool voluntarily capped their hashing power at 39.99% and requested other pools to follow in order to restore trust in the network.
